

MATH45101 - 2007/2008

General Information

- Title: Perturbation Methods in Fluid Mechanics
- Unit code: MATH45101
- Credits: 15
- Prerequisites: MATH34001 (MATH30211 in 2006-2007) *Applied Complex Analysis*, MATH34011 (MATH30241 in 2006-2007) *Asymptotic Expansions and Perturbation Methods*.
- Co-requisite units: None
- School responsible: Mathematics
- Members of staff responsible: Prof. [Anatoly Ruban](#)

Specification

Aims

To demonstrate the power and the beauty of modern asymptotic methods via discussing main ideas and approaches used in the theory of asymptotic expansions to simplify and to solve different mathematical problems which involve large or small parameters.

Brief Description of the unit

The development of the theory of asymptotic expansions, which serves as a foundation for perturbation methods, is one of the most important achievements in applied mathematics in the twentieth century. Perturbation methods represent a very powerful tool in modern mathematical physics and is particular, in fluid dynamics. This course unit will introduce students to a range of modern asymptotic techniques and illustrate their use in fluid flow analysis.

Learning Outcomes

On successful completion of the course unit the students will acquire thorough understanding of fundamental ideas used in the theory of asymptotic expansions and will develop appropriate practical skill in applying asymptotic methods for analysing mathematical and physical problems with small or large parameters. It is expected that the level of their knowledge in the field will be sufficient to start their own research in modern aspects of the asymptotic theory.

Future topics requiring this course unit

None.

Syllabus

1. Asymptotic expansions. Taylor expansion as a conventional converging power series and as an example of an asymptotic expansion. Asymptotic expansions for definite integrals with the upper or lower limits of integration depending on small or large parameters. Functions defined by real integrals. Laplace's method for definite integrals the integrand being of the form $f(t)\exp(\lambda t)$, where the parameter λ is large; Watson's Lemma. Generalisation for functions defined by contour integrals. Method of Steepest Descent. Applications. [4 lectures]
2. Regular asymptotic expansions for functions depending on the coordinate x , scalar or vector, and on a small parameter ε . Solution of ordinary and partial differential equations with small parameters. Examples from Fluid Dynamics. Ackeret formula for inviscid supersonic flows. Thin aerofoil theory for subsonic flows. [4]
3. Singular perturbations (algebraic example). Notion of the boundary layer. Inner and outer solutions. Overlap region. Matching of the asymptotic expansions. Ordinary differential equations with singular perturbations. Methods to determine location of the boundary layer. [4]
4. Method of multiple scales. Quasi-periodic solutions of second order ordinary differential equations developing non-uniformity at large time. Uniformly valid solutions. Amplitude equations. WKB Method. Turning point problems, and analysis of transition layers. [4]
5. Large Reynolds number solutions of the Navier-Stokes equations. Blasius boundary layer on a flat plate surface. Non-uniformities of the Blasius solution near the flat plate leading edge. Second order approximation for the solution near the

trailing edge. Triple-deck theory for the trailing edge flow. Self-induced separation of the boundary layer in supersonic flow. Principle of dominant balance, 'inspector's analysis'. Linear solutions for the triple-deck equations. Supersonic and subsonic corner flows. [8]

Teaching and learning methods

Two or three lectures each week (30 in all) and fortnightly examples classes.

Assessment

Mid-semester coursework: weighting 15%

End of semester examination: two and a half hours weighting 85%

Arrangements
